(54) Title: METHOD FOR THE DETECTION OF CANCER

(57) Abstract: A method for the early diagnosis, prognosis or clinical monitoring of cancer disease based on the quantitation of DNA in a plasma sample from a cancer patient, a subject with cancer susceptibility or an individual at risk of developing cancer.

WO 2004/057024 A1

**METHOD FOR THE DETECTION OF CANCER**

The present invention provides a method in vitro for the early diagnosis, prognosis and monitoring of cancer, or for the determination of the risk of development of cancer. The method of the invention is based on the quantification of DNA in a plasma sample through PCR amplification.

**5 BACKGROUND ART**

A number of scientific or patent publications describe methods for detecting cancer based on the identification of specific genetic alterations of circulating DNA or RNA.

10 US 5 496 699 discloses a method for detecting mutations in nucleic acid sequences, in particular the sequence of the K-ras gene, in biological fluids such as blood, serum or plasma.

US 5 068 175 discloses a method for detecting the presence of ras oncogene related malignancies in which said gene is quantified in serum or plasma samples.

15 WO01/42504 discloses the determination of extracellular nucleic acid, for example DNA of K-ras and APC genes, in serum or plasma samples, for the evaluation of the risk factor related with a number of neoplastic diseases.

WO02/18652 discloses a method of quali/quantitative detection of human telomerase RNA and telomerase reverse transcriptase RNA in plasma  
20 or serum for the diagnosis, monitoring, treatment or evaluation of a number of neoplastic diseases.

In principle, the methods for the molecular characterization of gene alterations have low sensitivity and require the analysis of a large panel of gene markers to obtain an acceptable information level.

25 Recently, a method has been reported for the quantitation of circulating naked DNA in plasma from lung cancer patients, based on a colorimetric

assay able to discriminate between patients and healthy subjects and to early detect the relapse of the disease during follow-up (Sozzi, G. et al., Cancer Research 61, 4675-4678, June 15, 2001). The colorimetric techniques (e.g. DNA Dipstick) for the quantitative evaluation of circulating DNA, however, are limited by a narrow linearity in the range 0.1-10 ng/ml, and by reduced sensitivity to lower values. In addition the test reading relies on subjective evaluation.

A more recent paper (Hsueh-Wei Chang et al., Journal of the National Cancer Institute, Vol. 94, No. 22, November 20, 2002) suggested the analysis of DNA concentration in plasma samples and the analysis of SNPs for the detection of neoplastic disease, in particular ovarian cancer. DNA quantitation has been carried out by analysis of fluorescence intensity generated by the dye PicoGreen® linked to double-stranded DNA. The results show that, contrary to SNP analysis, the method used for measuring plasma DNA concentration is poorly sensitive and specific, and therefore is not suitable for the screening of population for neoplastic disease.

## SUMMARY OF THE INVENTION

The present invention provides a method for the quantitative determination of circulating DNA in a plasma sample from a cancer patient, a subject with familiar cancer susceptibility or at risk of developing cancer, which comprises:

- 1) extracting the DNA from the sample;
- 2) adding to the DNA preparation: a) a mixture of oligonucleotide primers suitable for PCR amplification of a fragment of the human telomerase reverse transcriptase (hTERT) gene, and b) an oligonucleotide probe, having at least one quencher and one reporter fluorophore at the 3' and 5' ends, annealing to a sequence within the region delimited by the primers,

in suitable conditions for carrying out a PCR reaction,

- 3) adding a heat-stable DNA polymerase with 5'-3' hexonuclease activity and amplifying the hTERT gene fragment;
- 4) measuring the produced fluorescence.

5 The relative amount of DNA present in the tested sample can easily be obtained by the detected fluorescence values by interpolation of a calibration curve obtained with known amounts of DNA.

According to a preferred embodiment, primers and probes are designed so as to amplify the fragment 13059-13156 of the hTERT gene (GenBank  
10 accession n. AF128893).

The described procedure, known as real-time PCR, can be automatically carried out using the apparatus GeneAmp 5700 Detection System (Applied Biosystem), which provides accurate quantitative DNA amplification through continuous optical monitoring of the fluorogenic PCR reaction, and it can  
15 quantify up to 1 genome-equivalent, corresponding to 6 pg of genomic DNA.

The quantitation method of circulating DNA according to the invention can be applied to the early diagnosis, prognosis or clinical monitoring of patients with different kinds of cancer, including colon-rectum, head-neck, liver and pancreas cancer, particularly lung cancer. The method of the  
20 invention can also be used for the determination of the risk or likelihood of developing cancer in healthy subjects exposed to environmental or life-style risk-factors such as, in case of lung cancer, cigarette smoking. An increase in plasma DNA of these subjects is predictive of increased risk and therefore should prompt to repeat the test on an independent plasma sample, or to more  
25 thorough and specific clinical investigations.

## DETAILED DESCRIPTION OF THE INVENTION

A simple, accurate method in vitro has been found for the determination of the presence of a neoplastic disease or for the evaluation of the risk

connected with development of cancer, by quantitation of plasma DNA using the real-time PCR technique. More precisely, the invention provides a method for the quantitation of circulating DNA by continuous optical monitoring of a fluorogenic PCR reaction carried out on a plasma sample, using as primers and probes oligonucleotides which couple with the human telomerase reverse transcriptase (hTERT) gene. The amplification rate of hTERT is used as an indication of the DNA total amount in the tested sample.

The procedure has been validated in a large case-control study (200 subjects) involving patients with early stage lung cancer, in which during follow-up plasma DNA levels were determined after cancer resection, and healthy, heavy smokers matched by age, sex and smoking habits. The results of the study show that 1) the method of the invention has high specificity and sensitivity, as evidenced by the AUC and ROC curves (global value: 0.94, interval 0.907-0.973), 2) in patients, including those with very early stage cancer (stage IA), the values of circulating plasma DNA are approx. 8 fold higher than those found in healthy subjects, 3) in patients monitored during cancer resection follow-up, the DNA levels rapidly decrease down to a value similar to that observed in healthy subjects; in contrast, an increase up to 20 fold has been found in individuals with recurrent cancer or metastasis.

Although the highest sum of sensitivity (90%), specificity (86%), positive predictive value (PPV-90%) and negative predictive value (NPV-90%) was obtained with a DNA concentration value of 9 ng/ml, the confidence intervals (CIs) around these diagnostic indicators overlap with those of adjacent concentrations. The selection of the optimal cutpoint will therefore have to acknowledge this variability. The value of 25 ng/ml is the only cut-point shown with sensitivity that does not overlap with that of other cut-points, although it shows a low sensitivity (46%, 95% CI, 36%, 56%).

The magnitude of reported ORs (Odd Ratios) proves the strong

association between plasma DNA concentration and NSCLC risk, despite wide confidence limits. Similar OR values were never previously reported for any biological marker and could be of substantial benefit in clinical practice.

Increased amounts of circulating plasma DNA were observed in samples from any stage and tumor size. This is particularly relevant for small lesions, whose systematic detection could help reducing lung cancer morbidity and mortality.

One important aspect of the quantitative analysis provided by the invention is the possibility to follow longitudinal changes after cancer resection. The data available on 35 cancer patients showed a rapid decrease of circulating DNA values after lung resection. On the contrary, no decreasing or increasing levels of plasma DNA identified subjects with recurrence of their disease (24.7 ng/ml vs. 7.1 ng/ml in cancer-free patients,  $p=0.002$ ), suggesting that quantification of plasma DNA might represent a novel approach to monitor surgical patients or assess treatment efficacy after chemoradiotherapy.

To explore the possible modulation of free DNA release by smoking exposure, 20 never smokers over 55 yrs of age were analysed: their median DNA value was 0.61 ng/ml. The same analysis, carried out on the high-risk group from the case-control study (heavy smokers of age above 50, with exposure to smoke >20 pack/year) showed an average value of 4.6 ng/ml. These results indicate very low amounts of free circulating DNA in unexposed people.

The results of the clinical studies show the effectiveness of the method for the quantitation of circulating DNA of the invention in the early diagnosis of lung cancer in high-risk subjects, in particular in heavy smokers.

## DESCRIPTION OF THE FIGURES

**Figure 1.** Amplification plots of the real time quantitative PCR for hTERT in plasma DNA from NSCLC patients (A) and control samples (B). The relative amount of plasma DNA is much higher in patients samples (left plots)

compared with controls (right plots).

Calculation of the amounts of plasma DNA is based on the cycle number, where fluorescence of each reaction passes the threshold (CT), which is set to the geometric phase of the amplification above the background. The X axis denotes the cycle number of a quantitative PCR reaction. The Y axis denotes the log of fluorescence intensity over the background ( $\Delta R_n$ ).

**Figure 2.** Box-plots of plasma DNA concentration in NSCLC cases and matched controls. The box is bounded below and above by the 25% and 75% percentiles, the median is the solid line in the box, the lower and upper error bars indicate 90% of values. Mini = minimum value detected, max = maximum value detected, sd = standard deviation

**Figure 3.** ROC curves for the diagnosis of NSCLC using plasma DNA values. Curve and area under the curve (AUC) estimated using the logistic procedure in SAS (Cary, NC).

## MATERIALS AND METHODS

### *Case and control series*

One-hundred consecutive cases of non small cell lung cancer (NSCLC), 81 men and 19 women, non previously treated with chemo-radiotherapy and included in the European Institute of Oncology (IEO) tissue bank from 2000 to 2001, were evaluated. One control was selected for each case, matched by sex, age and smoking habits.

Mean age  $\pm$  sd was 65.1  $\pm$  8.9 years in cases and 64.1  $\pm$  8.2 in controls, average smoking duration was 40.5  $\pm$  10.9 years in cases and 41.7  $\pm$  9.5 in controls. The population included 7 case-control pairs of never smokers. The 93 heavy smoker controls were selected among the participants to the IEO early detection program, whose chest spiral CT proved to be negative. Non smoking controls were recruited from healthy blood donors at the immuno-hematology unit of the Institute. The number of former smokers

differed slightly between cases and controls (28 cases and 11 controls).

One light and occasional smoker case (< 5 cigarettes per day) was matched to a never smoker. A mean within-pair difference of 1 year in age was statistically significant ( $p < 0.02$ ), suggesting the need to adjust for age in the analysis of plasma DNA as risk factor.

#### *Samples collection and DNA isolation*

A 7.5 ml sample of peripheral blood was EDTA collected from patients prior to surgery and from controls at the time of spiral CT examination, and stored at  $-140^{\circ}$ . Plasma separation and DNA extraction were performed as previously reported (25). The DNA purified from 1 ml of plasma was eluted in a final volume of 50  $\mu$ l of water. Testing of plasma DNA was performed without knowledge of the case / control status.

#### *DNA Quantification in Plasma*

To quantify the circulating DNA in plasma we used a real-time quantitative PCR approach based on the 5' nucleotide method. This methodology is based on continuous monitoring of a progressive fluorogenic PCR by an optical system (28,29). The PCR system uses two amplification primers and an additional, amplicon-specific, and fluorogenic hybridization probe whose target sequence is located within the amplicon.

The probe is labeled with two fluorescent dyes. One serves as a reporter on the 5'-end (VIC<sup>TM</sup> dye). Its emission spectrum is quenched by a second fluorescent dye at the 3'-end (TAMRA). If amplification occurs, the 5' to 3' exonuclease activity of the AmpliTaq<sup>®</sup> DNA polymerase cleaves the reporter from the probe during the extension phase, thus releasing it from the quencher (30). The resulting increase in fluorescent emission of the reporter dye is monitored during the PCR process.

Primers and probes were designed to specifically amplify the ubiquitous gene of interest, the human Telomerase Reverse Transcriptase (hTERT) single

copy gene mapped on 5p15.33. The amplicon size of the hTERT gene was 98 bp (position 13059-13156, of the GenBank as accession no AF128893). The sequences of the primers and of the probe were the following: primer forward: 5'-GGC ACA CGT GGC TTT TCG-3'; primer reverse: 5'-GGT GAA CCT  
5 CGT AAG TTT ATG CAA-3'; probe: VIC5'- TCA GGA CGT CGA GTG GAC ACG GTG-3' TAMRA.

Fluorogenic PCRs were carried out in a reaction volume of 50  $\mu$ l on a GeneAmp<sup>®</sup> 5700 Sequence Detection System (Applied Biosystem, Foster City, CA). Fluorogenic probe and primers were custom synthesized by  
10 Applied Biosystems. Each PCR reaction mixture consisted of: 25  $\mu$ l of TaqMan<sup>®</sup> Universal Master Mix Applied Biosystem; 0.67  $\mu$ l probe [15 mM]; 0.45  $\mu$ l primer forward [10 mM]; 0.45  $\mu$ l primer reverse [10 mM]; 18.43  $\mu$ l sterile water. 5  $\mu$ l of DNA solution was used in each real-time PCR reaction. Thermal cycling was initiated with a first denaturation step of 50°C for 2 min  
15 and then 95°C for 10 min. The thermal profile for the PCR was 95°C for 15 s and 60°C for 1 min. Data obtained during 50 cycles of amplification were analyzed.

Amplifications were carried out in 96-well plates in a GeneAmp<sup>®</sup> 5700 Sequence Detection System (Applied Biosystem). Each plate consisted of  
20 patient samples in triplicates and multiple water blanks as negative control. For construction of the calibration curve on each plate we used a standard TaqMan Control Human Genomic DNA at 10 ng/ $\mu$ l (Applied Biosystem) with appropriate serial dilutions at 50 ng, 5 ng, 2.5 ng, 0.5 ng, 250 pg, 50 pg and 10 pg. Linear amplification down to the last dilution point representing 10 pg of  
25 target DNA was obtained in each experiment (Correlation coefficient 0.999-0.995; slope 3.25-3.35).

All the data were analysed using the Sequence Detection System software of Applied Biosystem to interpolate the standard amplification curve

of DNA at known quantity with amplification CT of the unknown target sample thus obtaining the relative amount of DNA in the experimental sample.

For the follow-up study, all the consecutive plasma samples for each patient were simultaneously analysed in the same real-time PCR experiment to  
5 allow comparative quantification of samples along the observation time.

*Pathological and immunohistochemical methods*

Clinico-pathological data were available for all cases. There were 58 adenocarcinomas, 34 squamous cell carcinomas, 3 large cell carcinomas, 3 pleomorphic carcinomas, and 2 adenosquamous carcinomas. According to the  
10 WHO classification of lung adenocarcinoma (31), 19 (32.6%) showed acinar growth pattern, 19 papillary, 17 (29.3%) solid and 3 (5.2%) bronchioloalveolar. According to the revised lung cancer staging system (32), tumor stage was pT1 in 18%, pT2 in 55%, pT3 in 21% and pT4 in 6%; forty-seven per cent of patients were pN0, 20% pN1 and 33% pN2 or N3. Stage I accounted for 34%,  
15 IIB 25%, IIIA 33%, and IIIB/IVB 8%. In three cases, the analysis was performed only on mediastinal nodes metastases.

In every case, the occurrence of either tumor necrosis or lymphoid infiltrate was evaluated semi-quantitatively on a scale from absent to 2+ (1+ if  $\leq 50\%$ , and 2+ if  $> 50\%$  of the whole tumor). For immunohistochemical  
20 analysis, formalin-fixed and paraffin-embedded samples obtained at surgery were investigated for cell apoptosis-related (p53) and tumour growth (CD-117, Ki-67, and microvessel density) markers, according to previously refined methods (33). All cases were evaluated blindly without knowledge of the patients' identity, pathological diagnosis, clinical outcome or plasma DNA  
25 status. The percentage of p53-, EGFR-, CD117- and Ki-67-immunoreactive tumor cells was evaluated by scoring a minimum of 1,000 tumor cells in representative fields of immunostaining. Tumor neoangiogenesis was inferred by CD34 immunostaining of endothelial cells as previously described (34).

### *Statistical Methods*

The distribution of DNA values revealed a departure from normality that was mitigated using a logarithmic transformation. The log of the concentration was used for testing purposes, however untransformed values  
5 were used for reporting results.

Odds ratios (OR) and corresponding 95% confidence intervals were calculated using conditional logistic regression in SAS (Cary, NC, USA) to assess plasma DNA as a risk factor for NSCLC. A receiver-operating characteristic curve (ROC) was built to evaluate the diagnostic performance of  
10 plasma DNA concentrations. Each unique DNA value was used as cut-point to calculate sensitivity and specificity values defining the curve and the area under the curve (AUC). Standard errors were estimated separately as described in van der Schouw (35) in order to provide a 95% confidence interval for the area.

15 In cases, the possible association of DNA concentration with continuous clinical and pathologic parameters was explored calculating Pearson's or Spearman's correlation coefficients, depending on the distribution of the parameters (i.e. age and distribution of EGFR marker respectively). Comparison of median DNA plasma concentrations in patients with follow-up  
20 data was done using the Kruskal-Wallis test.

## **RESULTS**

### *Quantitative analysis of circulating plasma DNA in cancer patients and controls*

25 Figure 1 shows amplification plots of fluorescence intensity against the PCR cycle from plasma samples of cancer patients and matched controls. Each plot corresponds to the initial target DNA quantity present in the sample. The amplification curves shifted to the right, representing reduced target DNA quantity, clearly discriminate controls from cancer patients. The distribution

of plasma DNA concentration in cases and matched controls describes two distinct populations of values despite some overlapping (Figure 2). Median concentration in cases (24.3 ng/ml) was almost eight times the value detected in controls (3.1 ng/ml). Very high concentrations were observed only in cases, whereas at the other end of the distribution there were few cases with very low concentrations of DNA (i.e. 0.5 ng/ml). A greater variability of circulating DNA was observed in cases than in controls (see Figure 2).

*Plasma DNA concentration as risk factor for NSCLC*

An elevated concentration of circulating plasma DNA was associated with a higher risk of NSCLC. Tertile stratification showed that the risk increased exponentially when comparing subjects with plasma concentrations in the second and third tertile to those in the first tertile using conditional logistic regression (up to 85-fold, Table 1). When analyzed as continuous, a unit increase in plasma DNA (ng/ml) was associated with a 21% increase in NSCLC risk (OR=1.21, 95% CI=1.11, 1.31). Circulating DNA concentration was associated with age in cases (age coefficient when regressing the log of the plasma concentration=0.029, standard error=0.013, p=0.026). No association was observed between plasma DNA levels and smoking intensity or duration.

*Diagnostic performance of quantitative real-time PCR assay*

The area under the ROC curve shown in figure 3 was 0.94 (95% confidence interval 0.907-0.973) suggesting a strong discrimination power of the molecular assay. Shown in table 2 are few of the DNA concentration cut-points used to generate the curve with their sensitivity, specificity, positive predictive value and negative predictive value. The 95% confidence intervals around sensitivity estimates overlapped between the successive concentrations shown in table 2, except for the last two concentrations (20 and 25 ng/ml).

*Correlation of plasma DNA levels with clinico-pathological features*

Among the morphological and immunoistochemical markers analysed, a

significant association with EGFR expression as well as with microvessel density were observed (table 3). The proliferation marker Ki67 increased with increasing plasma DNA concentration, although the correlation was not statistically significant ( $p=0.15$ ). Age was the only clinical parameter that was significantly associated with DNA release in plasma. No association between plasma DNA levels and necrosis, lymphoid infiltration or growth patterns were observed.

*Change in plasma DNA levels during follow-up*

In 35 out of the 100 cancer patients evaluated for the amounts of plasma DNA prior to surgery for Stage I-II tumors, a second plasma sample was obtained and analysed to monitor changes in DNA levels during clinical follow-up, 3 to 15 months after surgery (median elapsed time 8 months). The overall median DNA concentration in follow-up plasma samples was 8.4 ng/ml, showing a clear trend versus reduction when compared to median baseline levels of 24.5 ng/ml ( $p<.0001$ ). When comparing these patients according to their clinical status, median DNA concentration at follow-up was significantly lower in 30 disease-free subjects as compared to 5 cancer patients showing relapse (7.1 ng/ml versus 24.7 ng/ml;  $p=0.002$ ).

**CLAIMS**

1. A method for determining the concentration of circulating DNA in a plasma sample from a cancer patient, a subject with cancer susceptibility or at risk of developing cancer, which comprises:

- 1) extracting the DNA from the plasma sample;
- 2) adding to the DNA preparation: a) a mixture of oligonucleotide primers suitable for PCR amplification of a fragment of the human telomerase reverse transcriptase (hTERT) gene, and b) an oligonucleotide probe, having at least one quencher and one reporter fluorophore at the 3' and 5' ends, able to anneal to a sequence within the region delimited by the primers, in suitable conditions for carrying out a PCR reaction,
- 3) adding a heat-stable DNA polymerase with 5'-3' hexonuclease activity and amplifying the hTERT gene fragment;
- 4) measuring the produced fluorescence.

2. A method according to claim 1, wherein the DNA concentration in the test sample is determined by interpolation of a calibration curve calculated with known amounts of DNA.

3. A method as claimed in claims 1-2, which further comprises comparing the concentration of circulating DNA to a reference concentration.

4. A method according to claim 3, wherein the reference concentration is from 9 to 25 ng/ml.

5. A method as claimed in claim 1, wherein said fragment of the human telomerase reverse transcriptase (hTERT) gene is from nt 13059 to nt 13156 of the sequence GenBank accession n. AF128893.

6. A method according to claim 5, wherein said fragment of the human telomerase reverse transcriptase (hTERT) gene is amplified using SEQ ID N.

1 and 2 as the primers forward and reverse, respectively, and SEQ ID N. 3 as the probe.

7. A method as claimed in claims 1-3, for the early diagnosis, prognosis or clinical monitoring of cancer patients.

5 8. A method as claimed in claims 1-3, for the evaluation of the risk of developing cancer in healthy individuals or individuals with familiar cancer susceptibility.

9. A method as claimed in claim 8, for the evaluation of the risk of cancer development in smokers.

10 10. A method as claimed in claim 1, wherein said cancer is lung, colon-rectum, head and neck, liver or pancreas cancer.

11. A method as claimed in claim 10, wherein said cancer is lung carcinoma.

- \*A\* document defining the general state of the art which is not considered to be of particular relevance
- \*E\* earlier document but published on or after the international filing date
- \*L\* document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
- \*O\* document referring to an oral disclosure, use, exhibition or other means
- \*P\* document published prior to the international filing date but later than the priority date claimed

- \*T\* later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
- \*X\* document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
- \*Y\* document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.
- \*Z\* document member of the same patent family

Date of the actual completion of the international search

13 May 2004

Date of mailing of the international search report

28/05/2004

Name and mailing address of the ISA

European Patent Office, P.B. 5818 Patentlaan 2  
NL - 2280 HV Rijswijk  
Tel. (+31-70) 340-2040, Tx. 31 651 epo nl,  
Fax: (+31-70) 340-3016

Authorized officer

Osborne, H

## INTERNATIONAL SEARCH REPORT

International Application No

PCT/EP 03/14719

C.(Continuation) DOCUMENTS CONSIDERED TO BE RELEVANT		
Category *	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
A	<p>KOK DE J B ET AL: "Real-time quantification of human telomerase reverse transcriptase mRNA in tumors and healthy tissues"</p> <p>CLINICAL CHEMISTRY, AMERICAN ASSOCIATION FOR CLINICAL CHEMISTRY. WINSTON, US, vol. 46, no. 3, March 2000 (2000-03), pages 313-318, XP002176598</p> <p>ISSN: 0009-9147</p> <p>the whole document</p>	1-11
A	<p>THIJSSSEN M A M A ET AL: "DIFFERENCE BETWEEN FREE CIRCULATING PLASMA AND SERUM DNA IN PATIENTS WITH COLORECTAL LIVER METASTASES"</p> <p>ANTICANCER RESEARCH, HELENIC ANTICANCER INSTITUTE, ATHENS,, GR, vol. 22, no. 1A, January 2002 (2002-01), pages 421-425, XP001083546</p> <p>ISSN: 0250-7005</p> <p>the whole document</p>	1-11
A	<p>WO 99/41406 A (UNIV MARYLAND)</p> <p>19 August 1999 (1999-08-19)</p> <p>claims 1-8</p>	1-11
A	<p>LO Y M D ET AL: "Plasma DNA as a prognostic marker in trauma patients"</p> <p>CLINICAL CHEMISTRY, AMERICAN ASSOCIATION FOR CLINICAL CHEMISTRY. WINSTON, US, vol. 46, no. 3, March 2000 (2000-03), pages 319-323, XP002251721</p> <p>ISSN: 0009-9147</p> <p>the whole document</p>	1-11
A	<p>KOPRESKI M ET AL: "Detection of tumor messenger RNA in the serum of patients with malignant melanoma"</p> <p>CLINICAL CANCER RESEARCH, THE AMERICAN ASSOCIATION FOR CANCER RESEARCH, US, vol. 5, August 1999 (1999-08), pages 1961-1965, XP002251904</p> <p>ISSN: 1078-0432</p> <p>the whole document</p>	1-11
A	<p>ANKER P ET AL: "DETECTION OF CIRCULATING TUMOUR DNA IN THE BLOOD (PLASMA/SERUM) OF CANCER PATIENTS"</p> <p>CANCER AND METASTASIS REVIEWS, KLUWER ACADEMIC PUBLISHERS, DORDRECHT, NL, vol. 18, no. 1, 1999, pages 65-73, XP009002719</p> <p>ISSN: 0167-7659</p> <p>the whole document</p>	1-11
